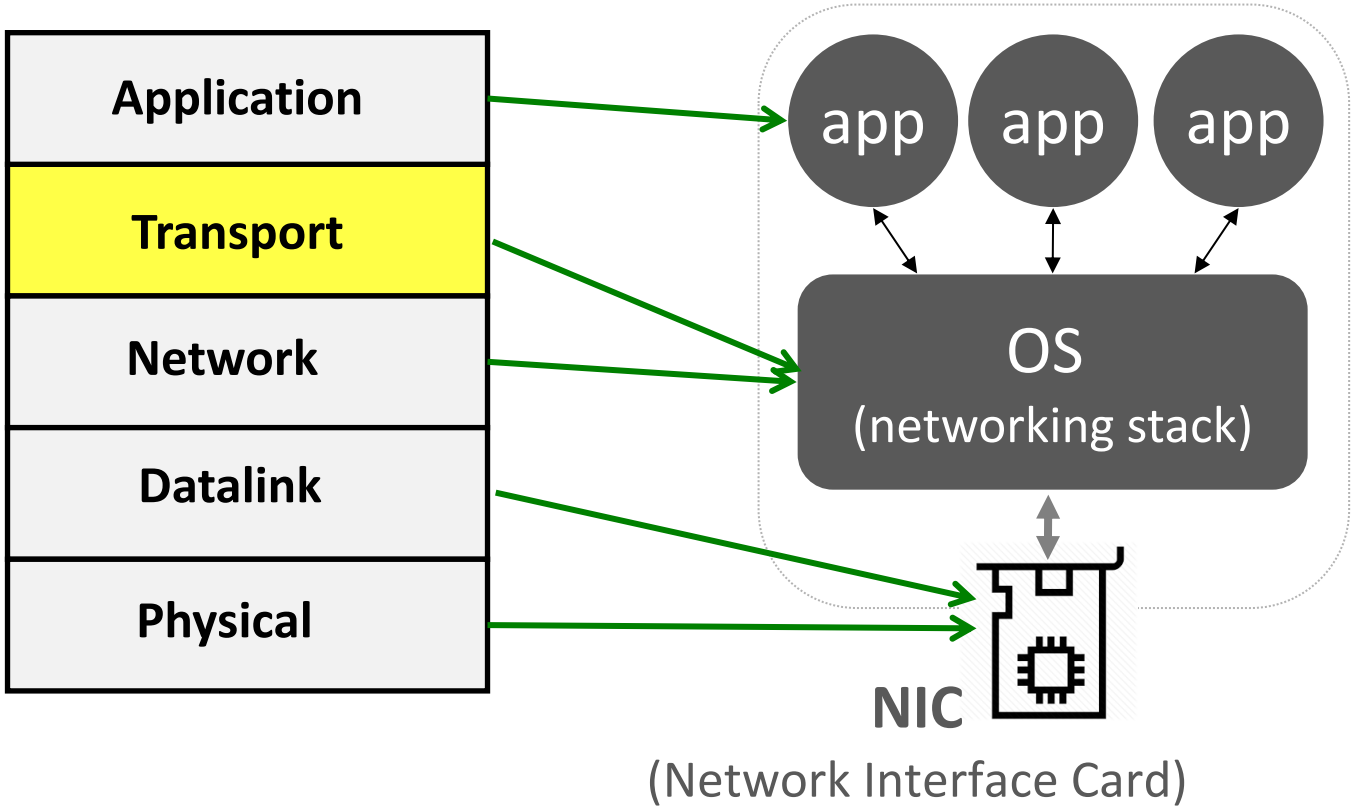
CS168.io

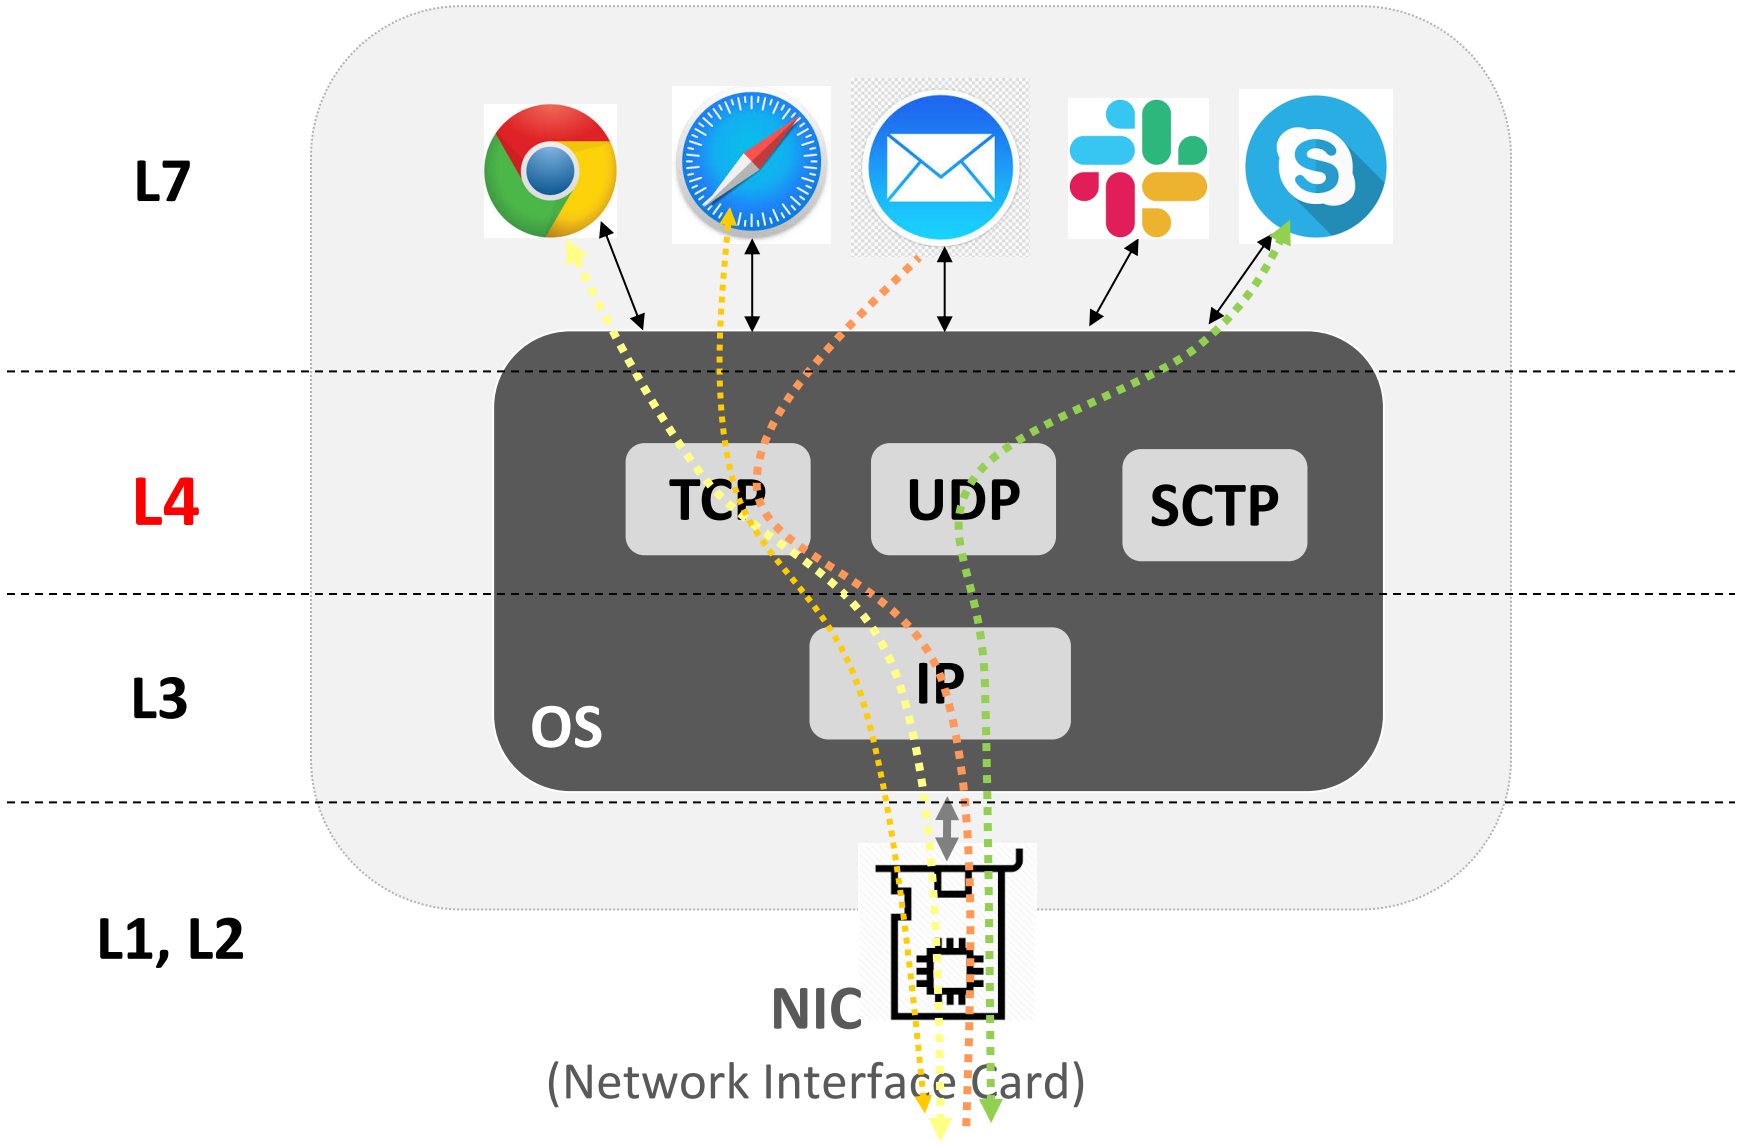
# Agenda

- What does the Transport layer do?
- The design of TCP

# Transport Layer

# Transport in our layered architecture





L7
L4
L3
L1, L2
TCP
UDP
SCTP
IP
OS
NIC
(Network Interface Card)

# Role of Transport Layer

- Bridging the gap between
  - **The abstractions application designers want**
  - **The abstractions networks can easily support**
- Could have been built into apps, but a common implementation makes app development easier

# Role of Transport Layer?

- **Application layer**
  - Communication for specific applications
  - E.g., File Transfer Protocol (FTP), Network Time Protocol (NTP), HyperText Transfer Protocol (HTTP), Internet Message Access Protocol (IMAP)
- Transport layer
  - *What do we need here?*
- Network layer
  - Logical communication between nodes
  - E.g., IP

# Role of Transport Layer?

- Application layer
  - Communication for specific applications
  - E.g., File Transfer Protocol (FTP), Network Time Protocol (NTP), HyperText Transfer Protocol (HTTP), Internet Message Access Protocol (IMAP)
- Transport layer
  - *What do we need here?*
- **Network layer**
  - Best-effort global packet delivery
  - IP

  - *What do we need here?*
- Network layer
  - Best-effort global packet delivery
  - IP

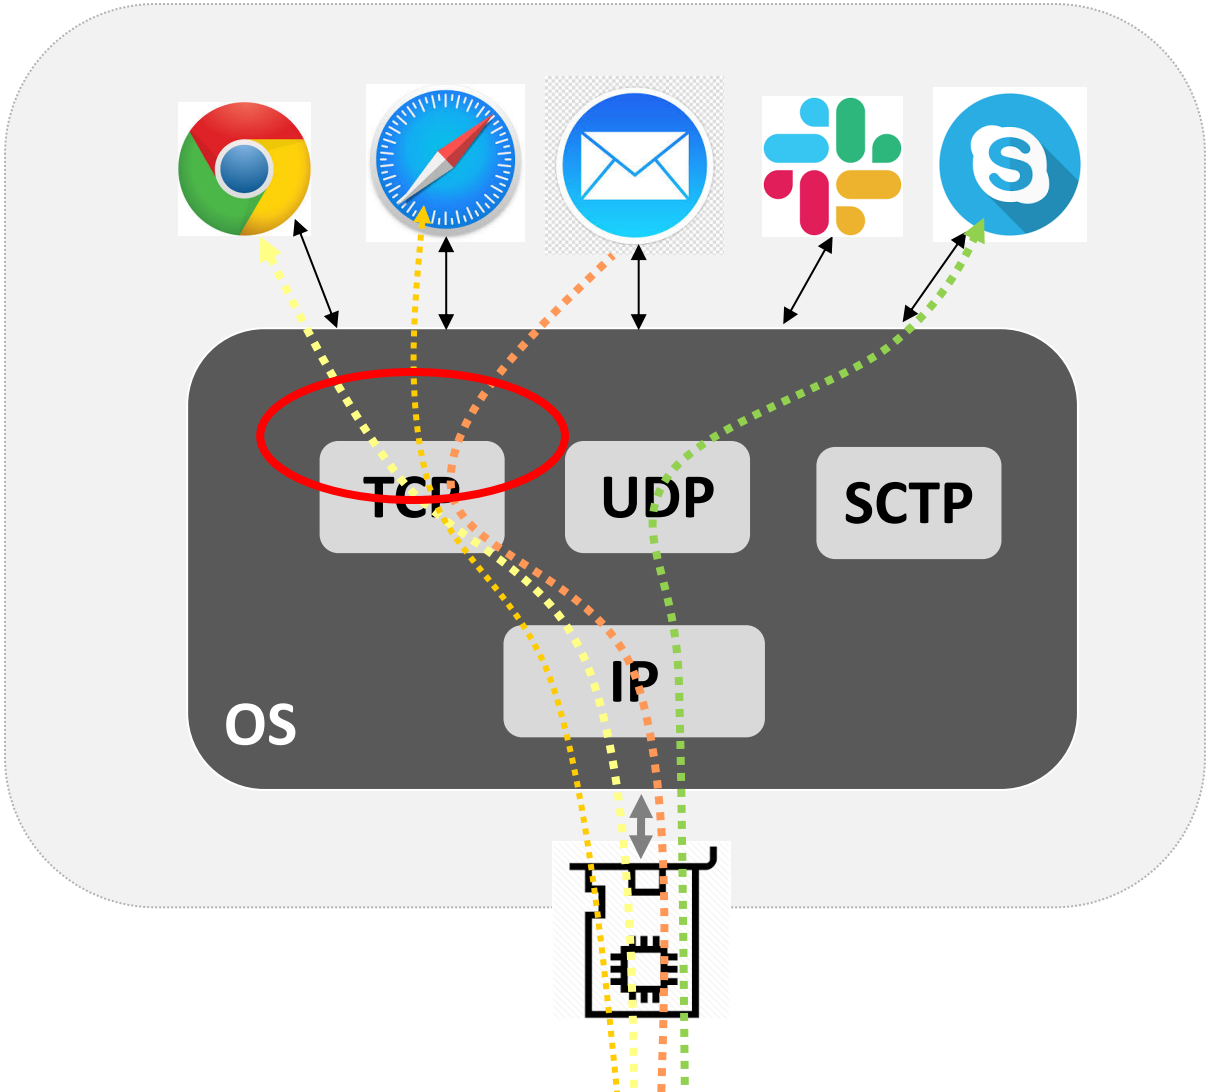
# What does the transport layer address?

- Demultiplexing
  - Identify app this data belongs to (lecture#3)
- Reliability
  - Last lecture
- Translate from packets to app-level abstractions
  - E.g., between bytestreams and packets (this lecture)
- Avoid overloading the receiver (this lecture)
- Avoid overloading the network (future lectures)

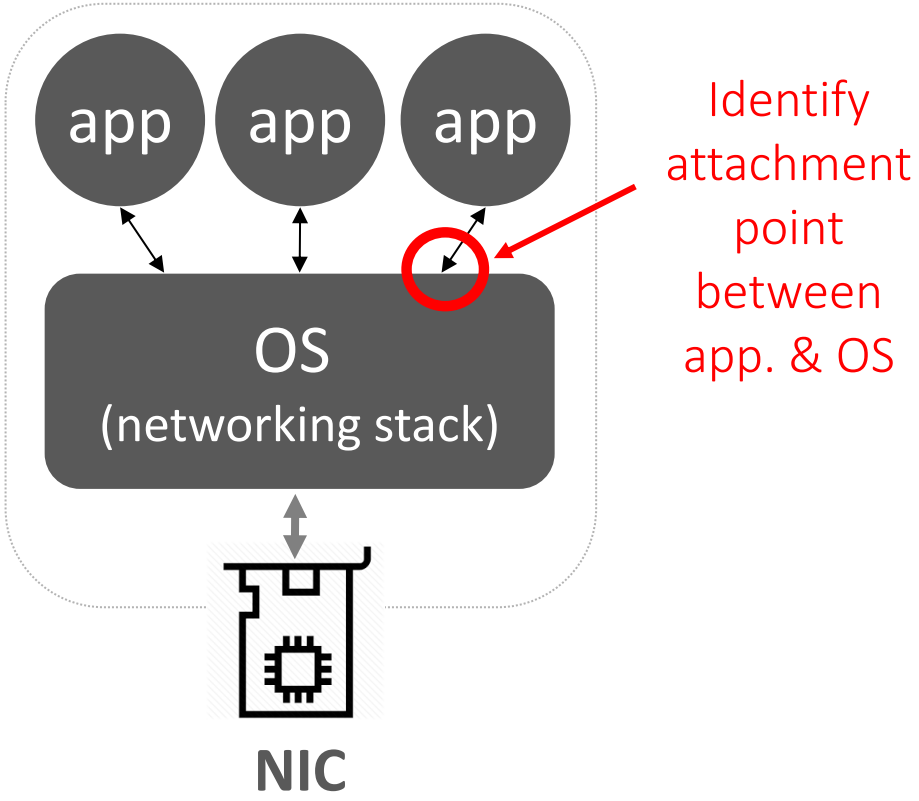
Let’s first talk about these issues in general

...and then how TCP addresses them

# Demultiplexing?



# Recall: logical ports



Place where app connects to the OS network stack

# Hence, demultiplexing

- Achieved by defining a field (“port”) that identifies the application
- Field is carried in a packet’s **L4 protocol header**

# Reliable Delivery

- Last lecture

  - We've identified our design building blocks
    - Checksums
    - ACK/NACKs
    - Timeouts
    - Retransmissions
    - Sequence numbers
    - Windows
  - And discussed tradeoffs in how to apply them
    - Individual vs. Full vs. Cumulative ACKs
    - Timeout vs. ACK-driven loss detection

# Application-layer abstractions

- Ideally, app doesn't see the gory details of the network
  - packets, ACKs, duplicates, reordering, corruption, ...
- Want a higher-level abstraction that meets app needs

# Application Abstractions

- **Reliable in-order bytestream** delivery (TCP)
  - Logical “pipe” between sender and receiver
  - Bytes inserted into pipe by sender-side app
  - They emerge, in order, at the receiving app

- **Individual message** delivery (UDP)
  - Unreliable (application responsible for resending)
  - Messages limited to single packet

# What does the transport layer address?

- Demultiplexing
  - Identify app this data belongs to (logical ports, lecture#3)
- Reliability
  - Last lecture (though TCP does things a little differently)
- Translate from packets to app-level abstractions
  - E.g., between bytestreams and packets
- Avoid overloading the receiver
- Avoid overloading the network

# How big should the window be?

- **Lecture#12:** Pick window size W to balance three goals
  - Take advantage of network capacity ("fill the pipe")
  - But don't overload the receiver (flow control)
  - And don't overload links (congestion control)

- **Lecture#12:** For the first goal: W x pkt_size ~ RTT x B
  - RTT is round-trip time and B is the bottleneck BW
  - This is **an upper bound** on the desired size of W

- Now consider the other two goals...

# Don’t overload the receiver

- Consider the transport layer at the receiver side
- May receive packets out-of-order but can only deliver them to the application in order
- Hence, the receiver must buffer incoming packets that are out of order
  - Must continue to do so until all “missing” packets arrive!
- Must ensure the receiver doesn’t run out of buffers

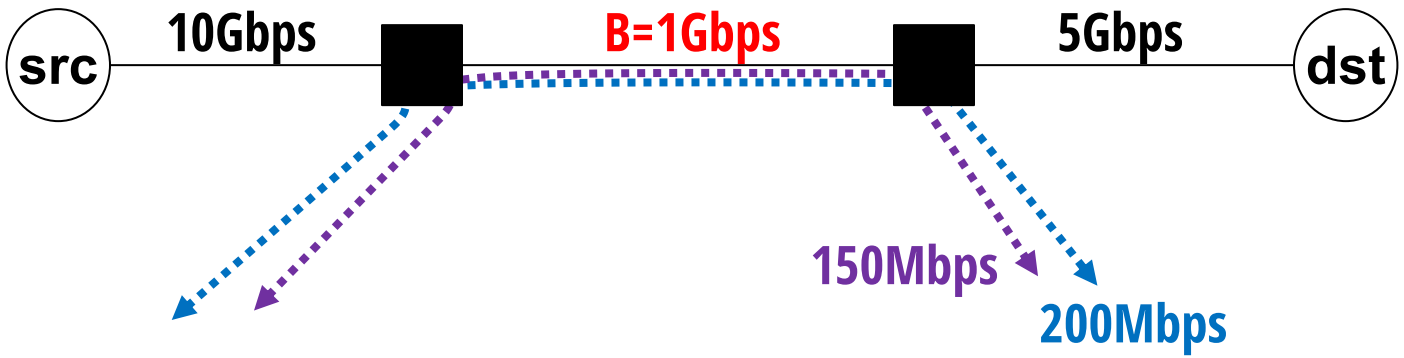
# Hence: Flow Control

The basic idea is very simple...

- Receiver tells sender how much space it has left
  - TCP calls this the **“advertised” window**
- Advertisement is carried in ACKs
- Sender adjusts its window accordingly
  - Packets in flight cannot exceed the receiver’s advertised window

# Don’t overload the network

- Previously: sender sets W to fully consume the bottleneck link bandwidth
  - I.e., sender is sending data at the rate of B
- In practice, bottleneck is shared with other flows
- Hence, sender should only consume *its share* of B
- But what is this share?



# Congestion Control

- The transport layer at the sender implements a congestion control algorithm that dynamically computes the sender's share of the bottleneck link BW
- TCP calls this the sender's **congestion window** (cwnd)
- Computed to balance multiple goals
  - Maximize my performance
  - Without overloading any link (avoid dropped packets)
  - While sharing bandwidth ”fairly” with other senders
- Topic for (multiple) future lectures

# How big should the window be?

- Pick window size **W** to balance three goals
  - Take advantage of network capacity ("fill the pipe")
  - But don't overload the receiver (flow control)
  - And don't overload links (congestion control)

- First goal:  W ~ RTT x B
- Second: W ~ receiver's advertised window
- Third: W ~ sender's congestion window (cwnd)

- Window size is set to the minimum of the above

# In practice

- A sender's cwnd should be <= RTT x B
- And it's difficult for the sender to discover B
- Hence, window size is the minimum of:
  - The congestion window computed at the sender
  - The receiver's advertised window

# Recap: what the transport layer tackles

- Demultiplexing
  - logical ports
- Reliability
  - acks, timeouts, windows, etc.
- Translation between abstractions
  - between packets and bytestreams (coming up)
- Avoid overloading the receiver
  - receiver's advertised window
- Avoid overloading the network
  - sender computes a congestion window

# What if your app doesn't want all these features?

- E.g., an application that doesn't need reliability
- E.g., an app that exchanges very short messages

- UDP: User Datagram Protocol
  - A no-frills, minimalist protocol
  - Only implements mux/demux

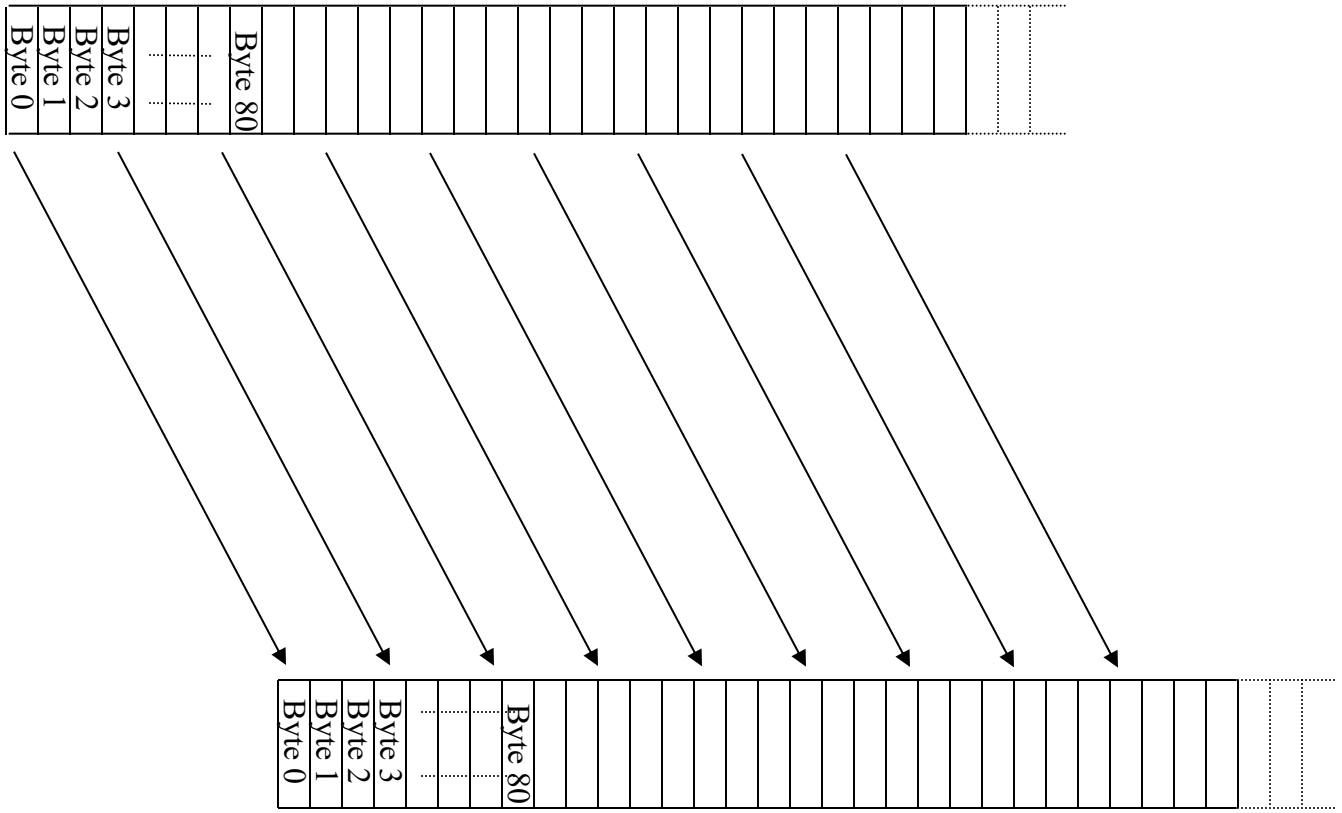
# TCP

# The TCP Abstraction

- TCP delivers a **reliable, in-order, bytestream**

# TCP “Stream of Bytes” Service…

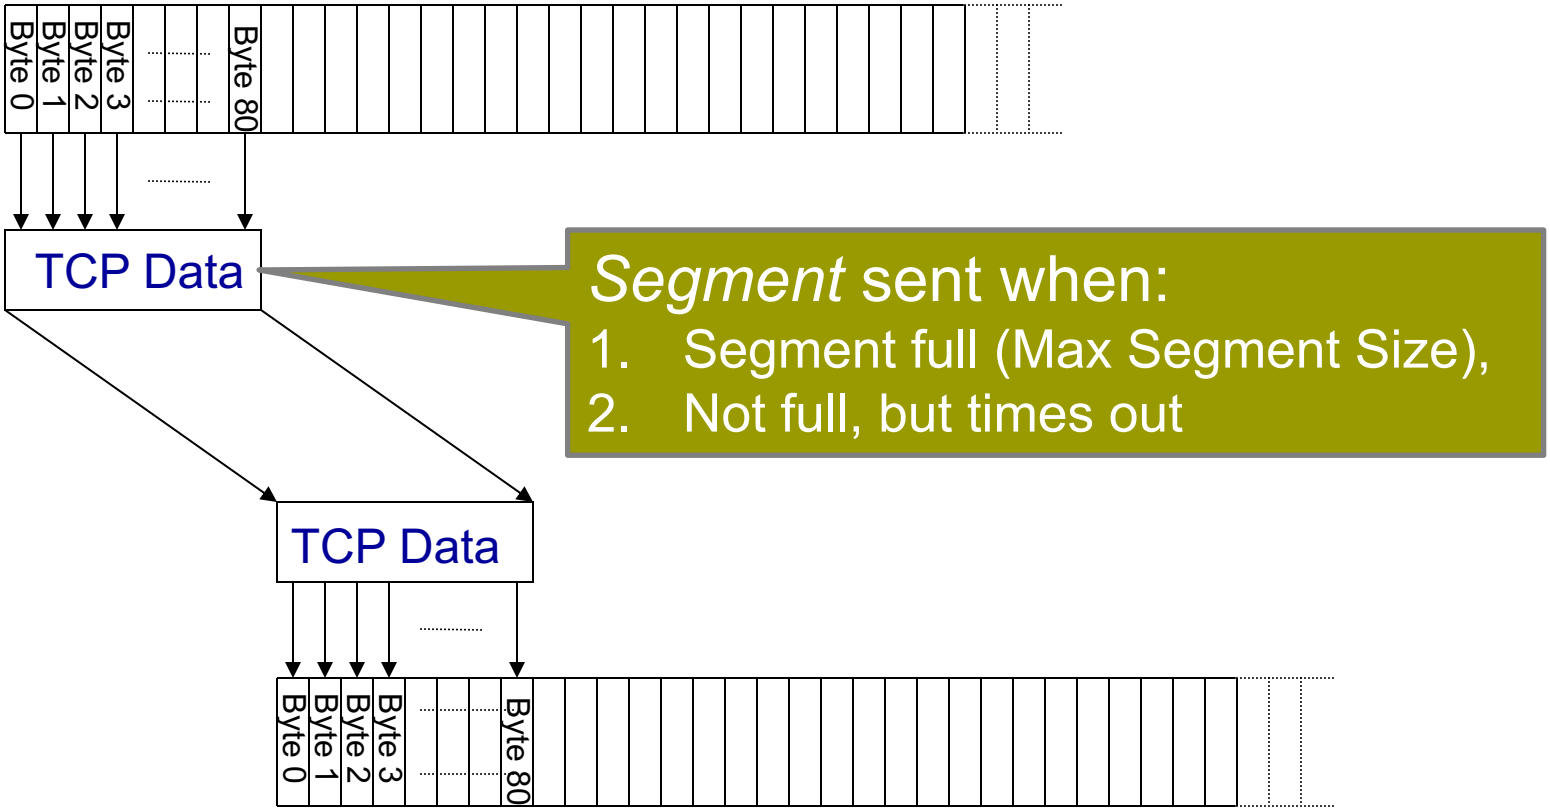
Application @ Host A



Application @ Host B

# … Implemented Using TCP "Segments"

Application @ Host A



*Segment* sent when:

1. Segment full (Max Segment Size),
2. Not full, but times out

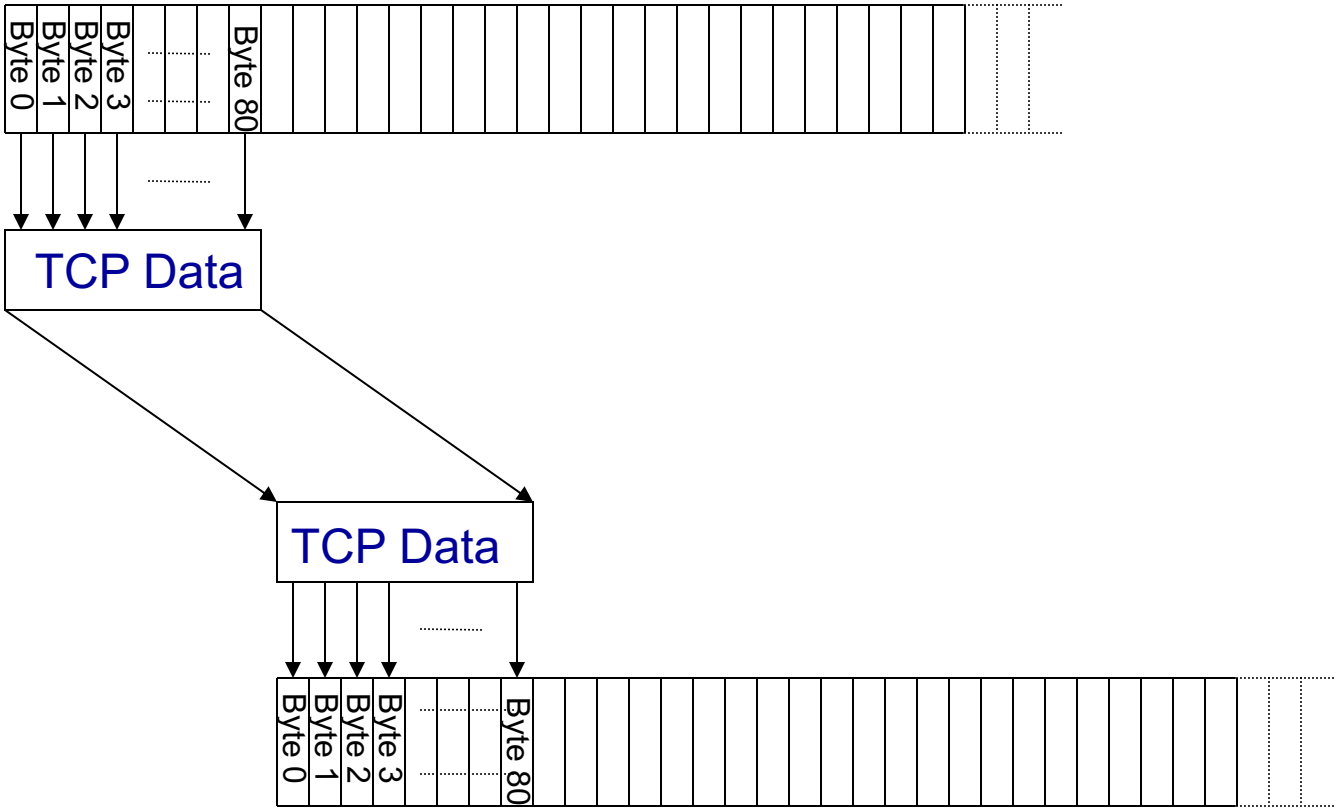
Application @ Host B

# TCP Segment

- TCP packet
  - IP packet with a TCP header and data inside
- IP packet
  - No bigger than Maximum Transmission Unit (MTU)
- TCP **segment**
  - No more than Maximum Segment Size (MSS) bytes
  - MSS = MTU – (IP header) – (TCP header)

# … Implemented Using TCP "Segments"

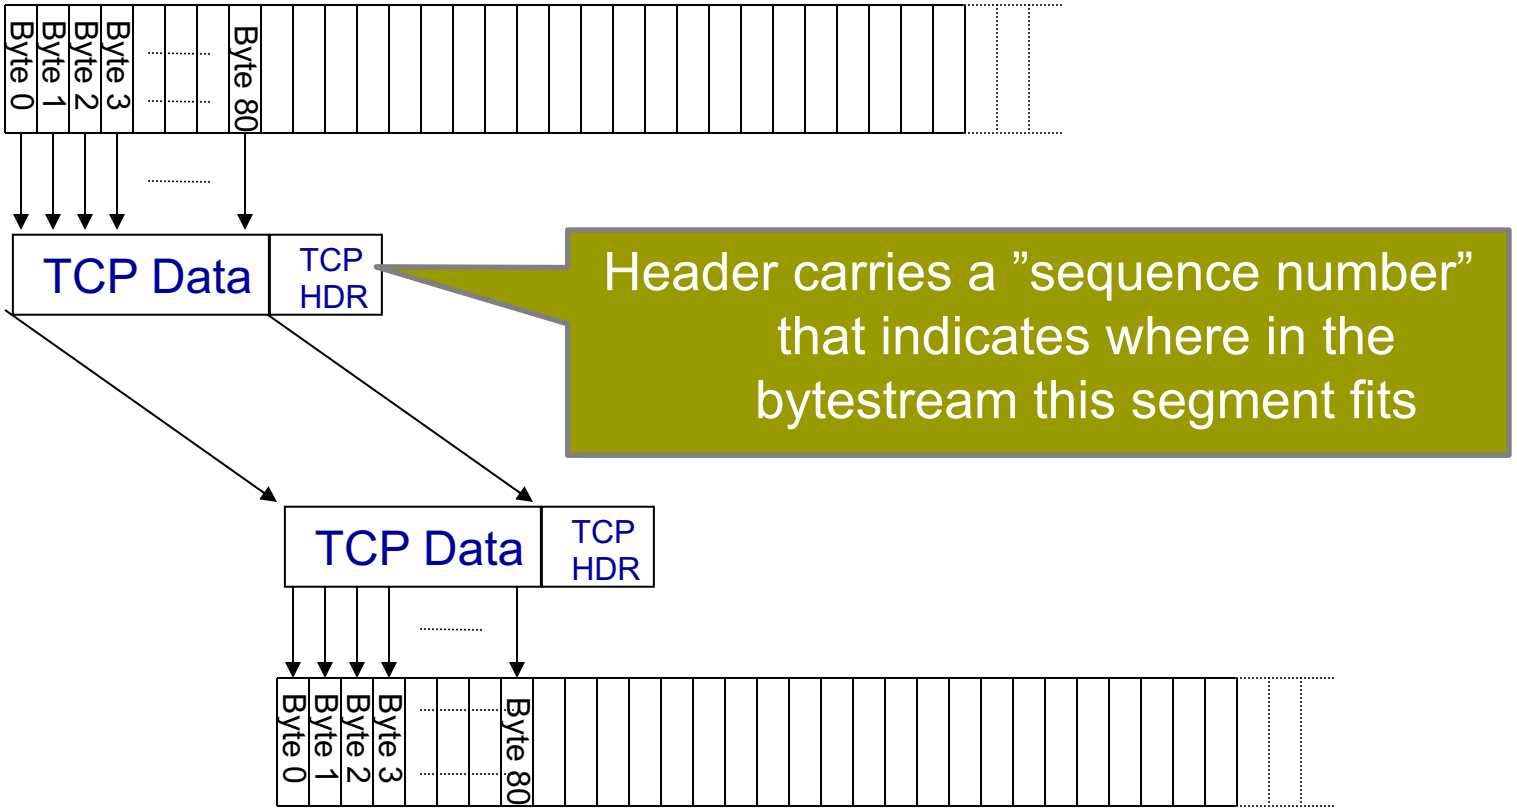
Application @ Host A



Application @ Host B

# … Described by TCP headers

Application @ Host A



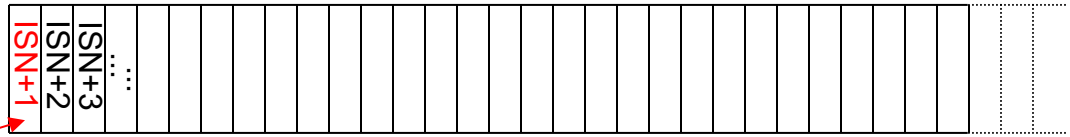
Application @ Host B

# Major Notation Change

- Previously we focused on packets:
  - Packets had numbers
  - ACKs referred to those numbers
  - Window sizes expressed in terms of # of packets
- TCP focuses on bytes. Thus,
  - Packets identified by the bytes they carry
  - ACKs refer to the bytes received
  - Window size expressed in terms of # of bytes
- You should be prepared to reason in terms of either

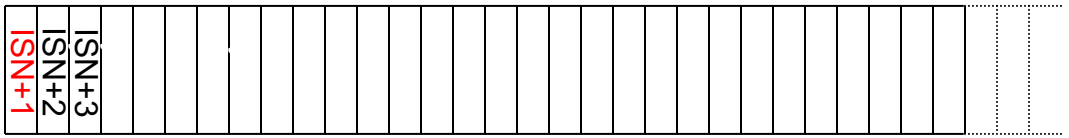
# TCP Sequence Numbers

Numbering starts with
an **ISN (Initial Sequence Number)**



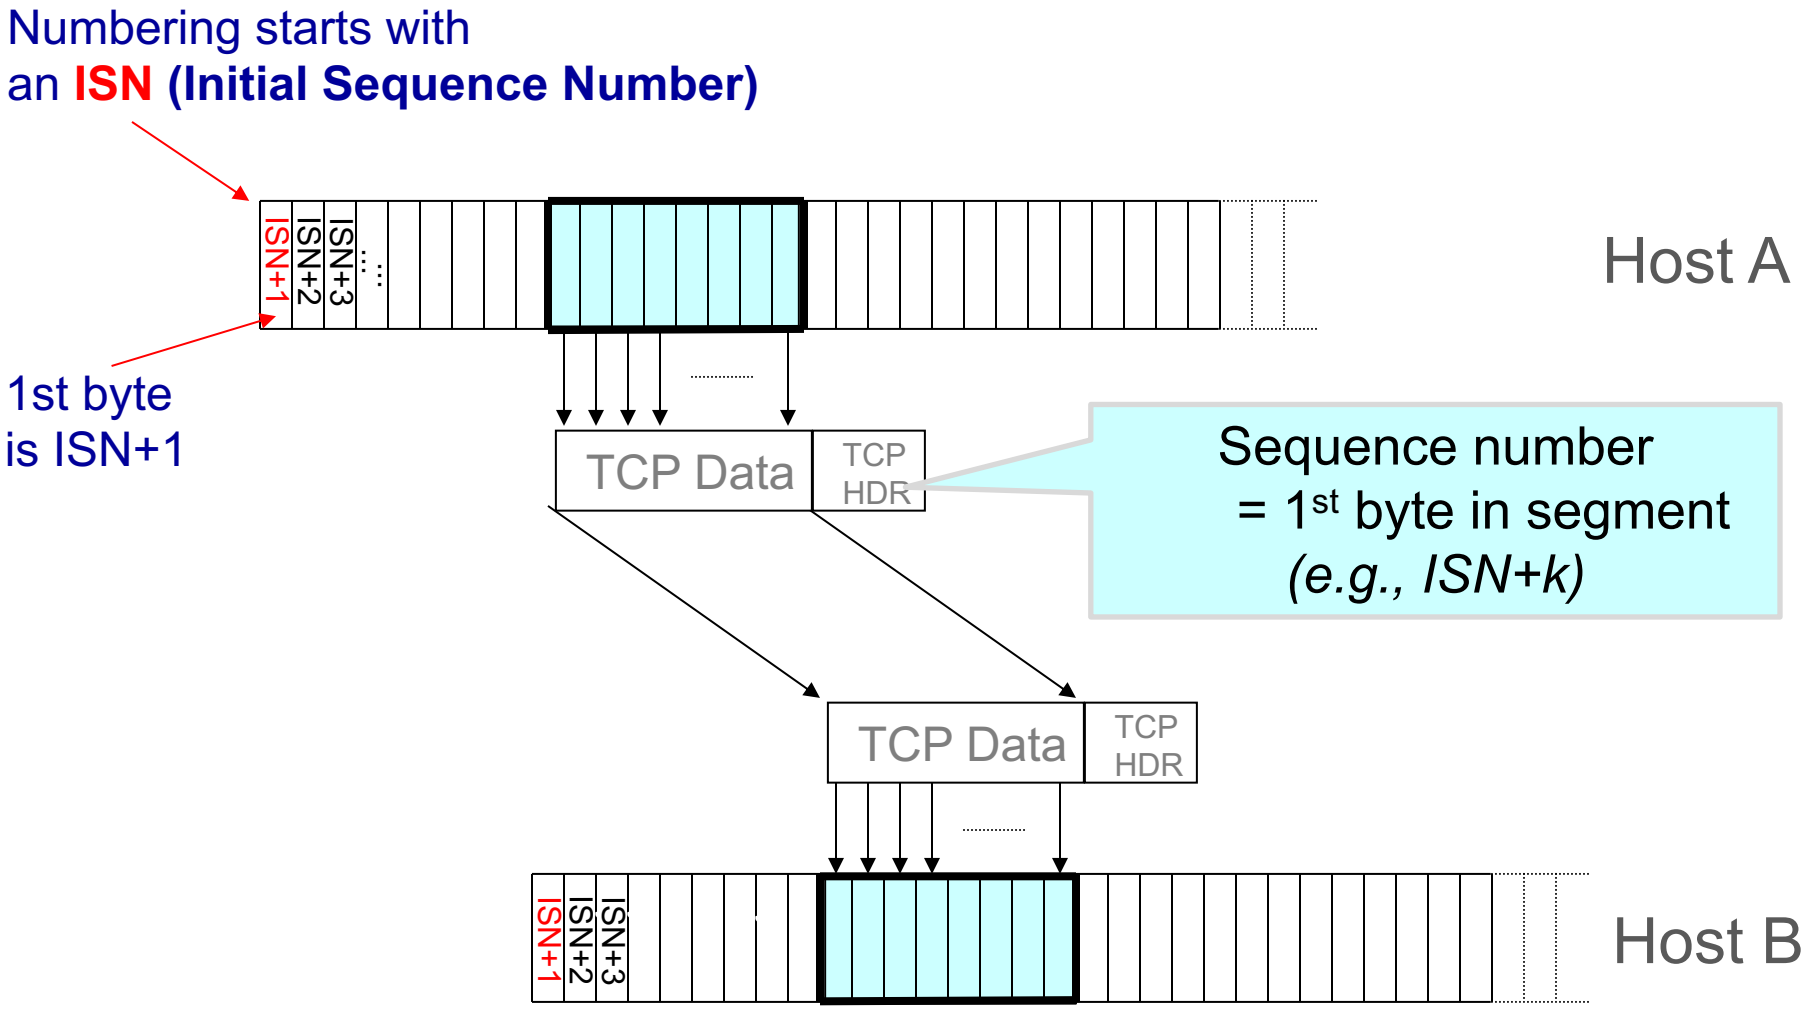
1st byte
is ISN+1

Host A

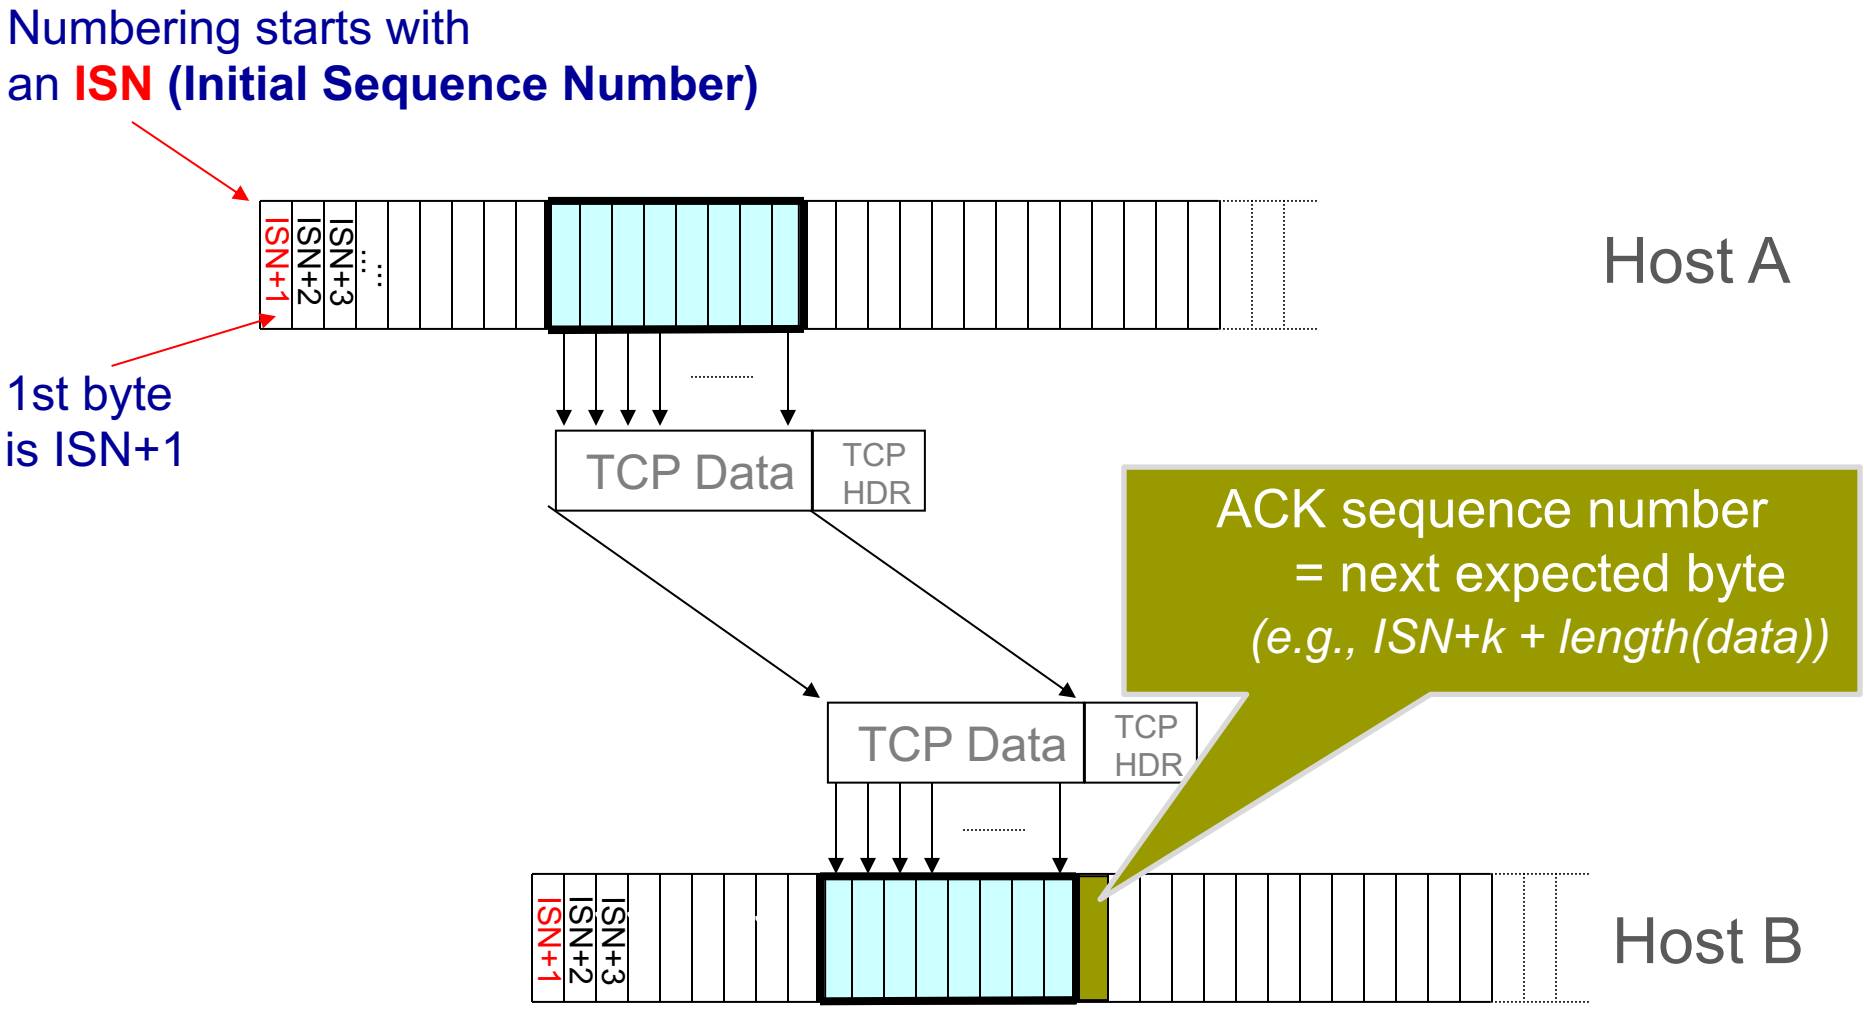


Host B

# TCP Sequence Numbers



# TCP Sequence Numbers



# The TCP Abstraction

- TCP delivers a **reliable, in-order, bytestream**
- Reliability requires keeping state
  - Sender: packets sent but not ACKed, related timers
  - Receiver: out-of-order packets
- Each bytestream is called a connection or session
  - Each with their own connection state
  - State is in hosts, not network!

# Note#1: TCP is “connection oriented”

- TCP includes a connection setup and tear-down step
  - Used to initialize connection state at both endpoints
  - Details coming up ...

# #2: TCP connections are full-duplex

- So far, we've talked about a connection as having a sender side and a receiver side
- But connections in TCP are full-duplex
  - Each side of the connection can be sender *and* receiver
  - I.e., A can send data to B, while B sends data to A
  - Simultaneously, over the same connection
  - Packets carry both data and ACK info
- We can usually ignore this point (for this class)
- Except when it comes to connection establishment
- Will return to this later ...

# The TCP Abstraction

- TCP delivers a **reliable, in-order, bytestream**
- TCP is connection-oriented
  - Per-connection state is maintained at sender & receiver

# Functionality

- Mux/demux among processes
- Reliability
- Flow control (to not overflow receiver)
- Congestion control (to not overload network)
- “Connection” set-up & tear-down

# Ports

- 16-bit port address space for TCP and UDP
- Some ports are “well known” (0-1023)
  - e.g., ssh:22, http:80
  - Services can listen on well-known port
  - Client (app) knows appropriate port on server
- Other ports are “ephemeral” (most 1024-65535):
  - Given to clients (at random)

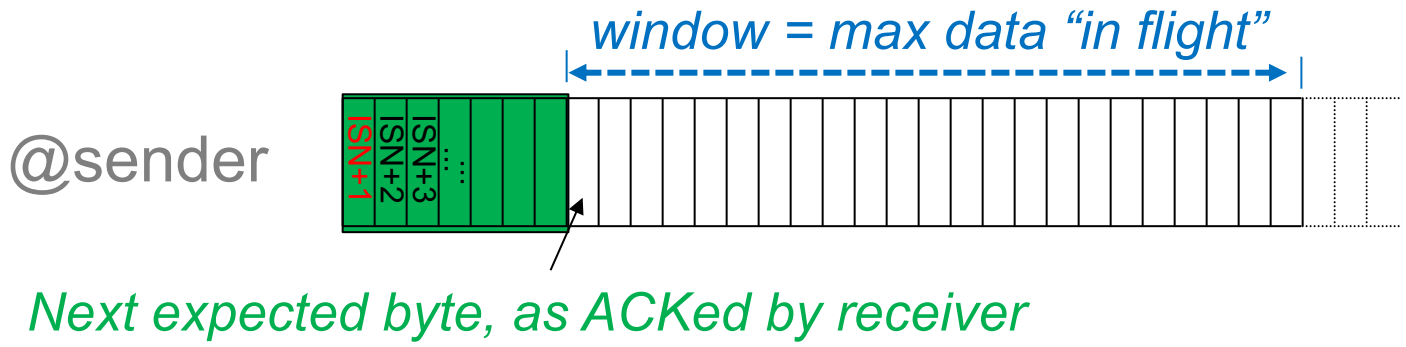
# Functionality

- Mux/demux among processes
- Reliability
- Flow control (to not overflow receiver)
- Congestion control (to not overload network)
- “Connection” set-up & tear-down

# How does TCP handle reliability?

Many of our previous ideas, with some key differences

- Sequence numbers are byte offsets
- Uses cumulative ACKs; with "next expected byte" semantics
- Uses sliding window: up to W contiguous bytes in flight



# How does TCP handle reliability?

Many of our previous ideas, with some key differences

- Sequence numbers are byte offsets
- Uses cumulative ACKs; with "next expected byte" semantics
- Uses sliding window: up to W contiguous bytes in flight
- Retransmissions triggered by timeouts and duplicate ACKs
- Single timer, for left hand side (1st byte) of the window
- Window size is a function of cwnd and advertised window
  - With special accounting for duplicate ACKs (future lecture)
- Timeouts are computed from RTT measurements
  - Covered in section

# ACKing and Sequence Numbers

- Sender sends packet
  - Data starts with sequence number X
  - Packet contains B bytes
    - X, X+1, X+2, ….X+B-1

- Upon receipt of packet, receiver sends an ACK
  - If all data prior to X already received:
    - ACK acknowledges X+B (because that is next expected byte)
  - If highest contiguous byte received is a smaller value Y
    - ACK acknowledges Y+1 (because TCP uses cumulative ACKs)

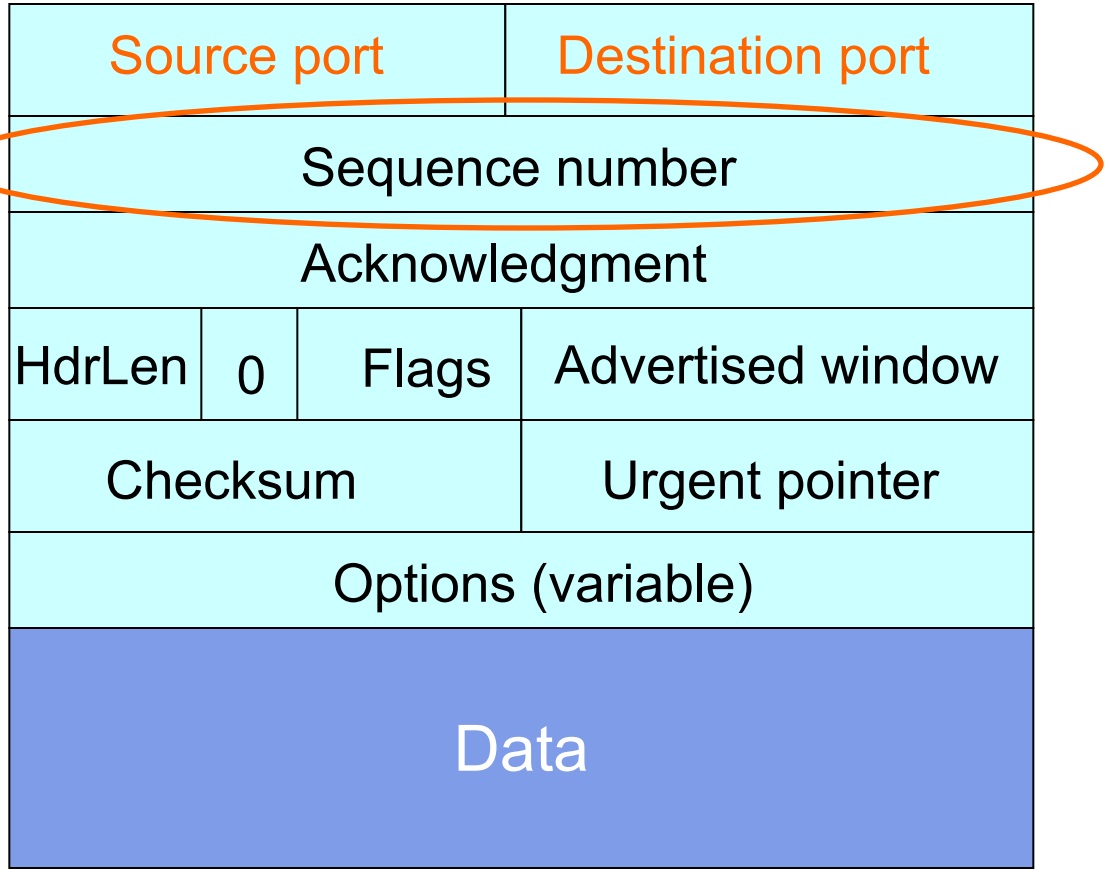
# Pattern (w/ only one packet in flight)

- Sender: seq number =X, length=B
- Receiver: ACK=X+B
- Sender: seq number =X+B, length=B
- Receiver: ACK=X+2B
- Sender: seq number =X+2B, length=B

- Seq number of next packet is same as last ACK

# TCP Header

Starting byte offset of data carried in this segment



# TCP Header

Acknowledgment gives sequence number just beyond the highest sequence number received **in order** (*i.e.*, next expected byte)

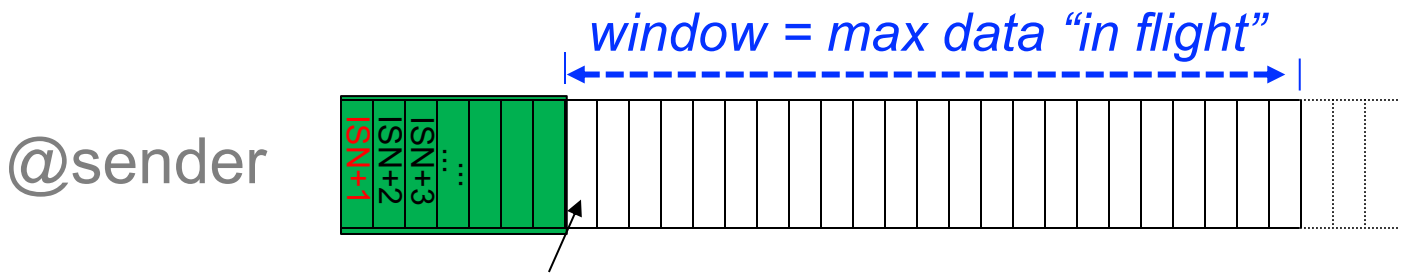
# Implementing Sliding Window

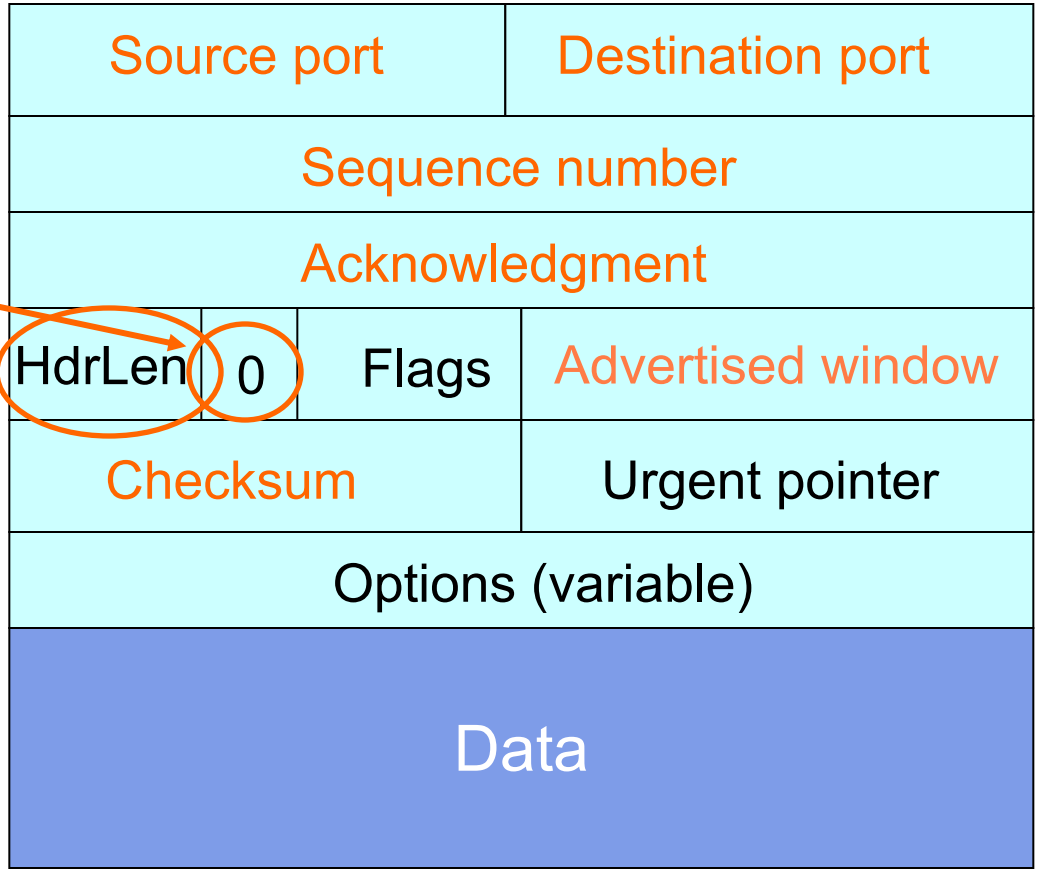
- Sender maintains a window
  - Data that has been sent but not yet ACK'ed
  - Window size = maximum amount of data in flight
- Left edge of window:
  - Beginning of unacknowledged data
- Right edge of window (ignoring congestion control)
  - Depends on the window advertised by receiver
  - Which depends on receiver's buffer space



# TCP Header: What's left?

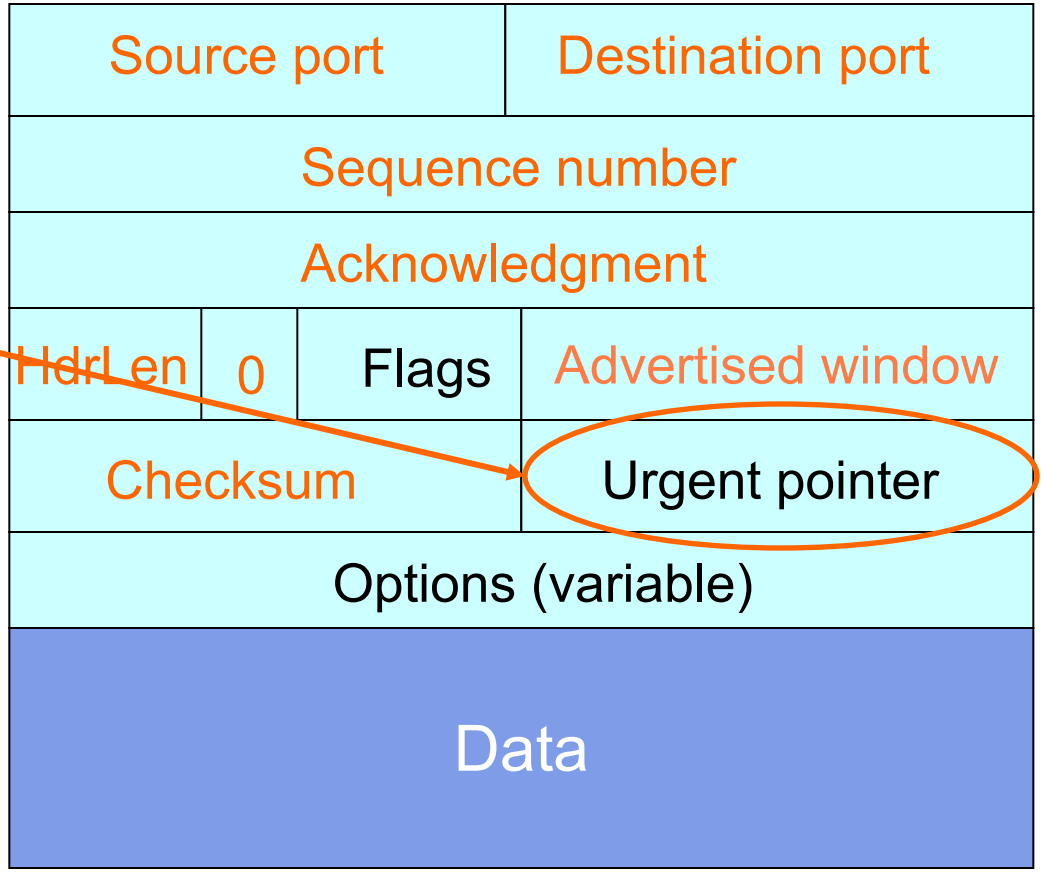
"Must Be Zero"
6 bits reserved

Number of 4-byte words in TCP header;
5 = no options



# TCP Header: What's left?

Used with **URG** flag to indicate urgent data (not discussed further)



# TCP Header: What's left?

Options

- Congestion control (future lecture)
- “Connection” set-up & tear-down

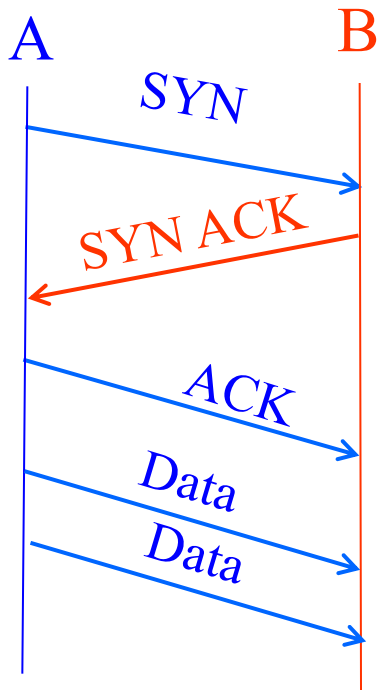
# TCP Connection Establishment and Initial Sequence Numbers

# Establishing a TCP Connection



**Each host tells its ISN to the other host.**

- Three-way handshake to establish connection
  - Host A sends a **SYN** to host B
  - Host B returns a SYN acknowledgment (**SYN ACK**)
  - Host A sends an **ACK** to acknowledge the SYN ACK

# TCP Header

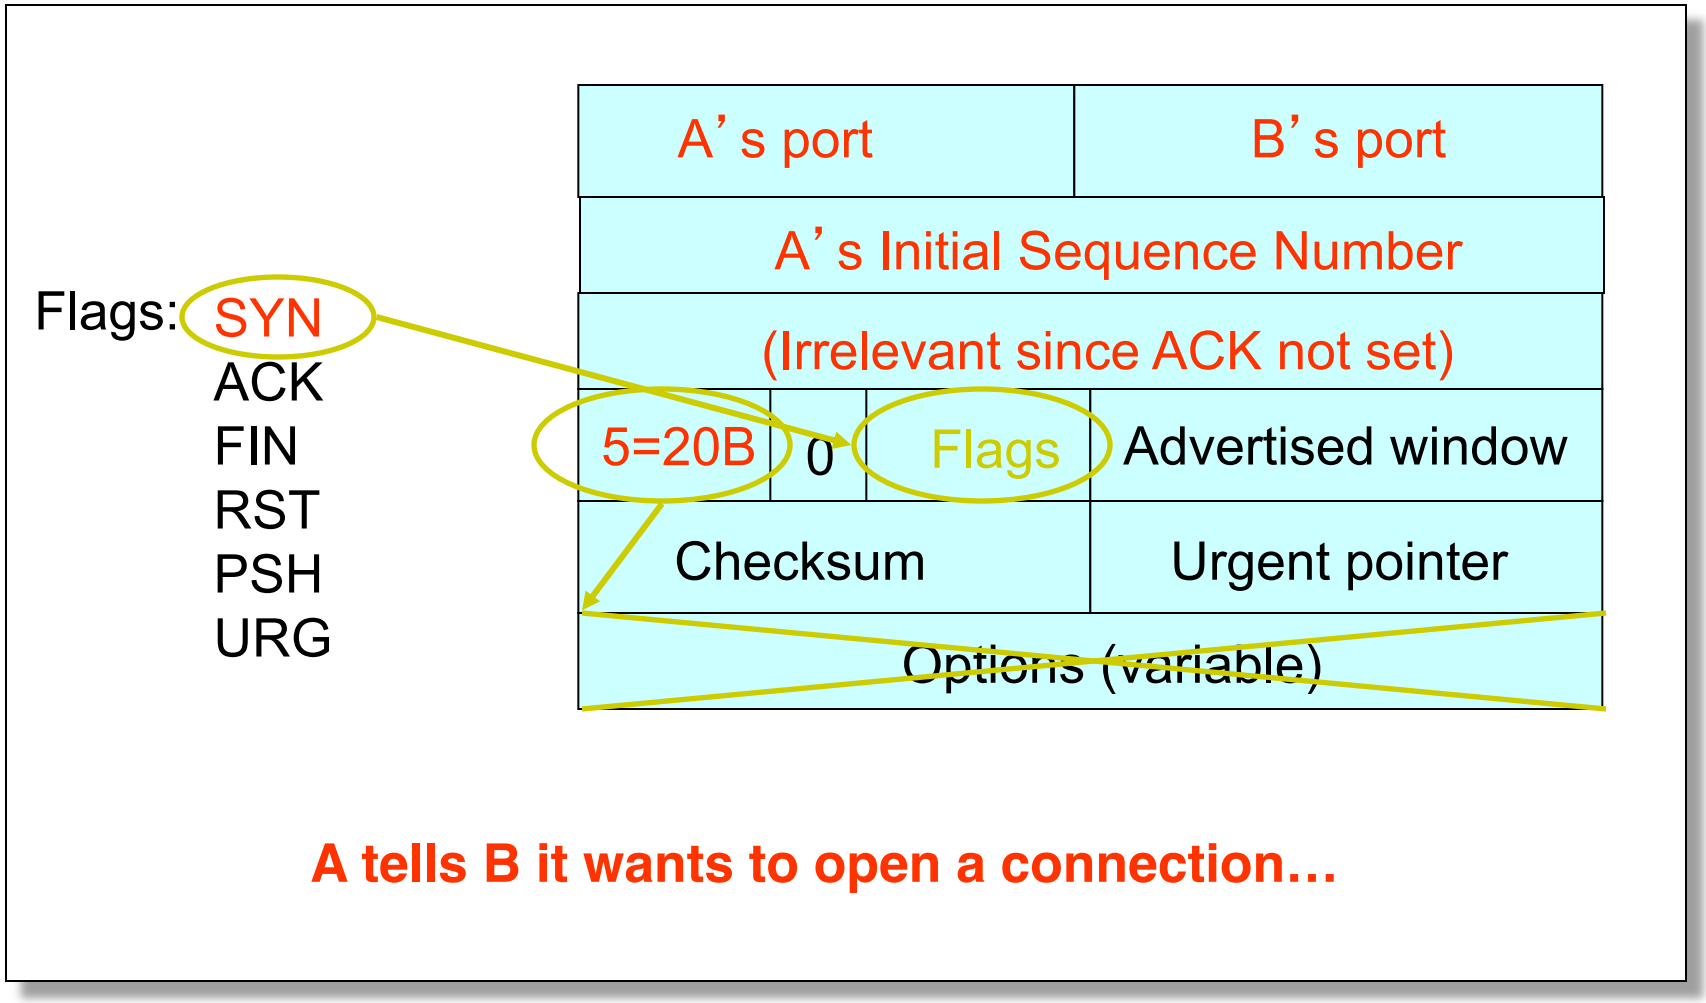
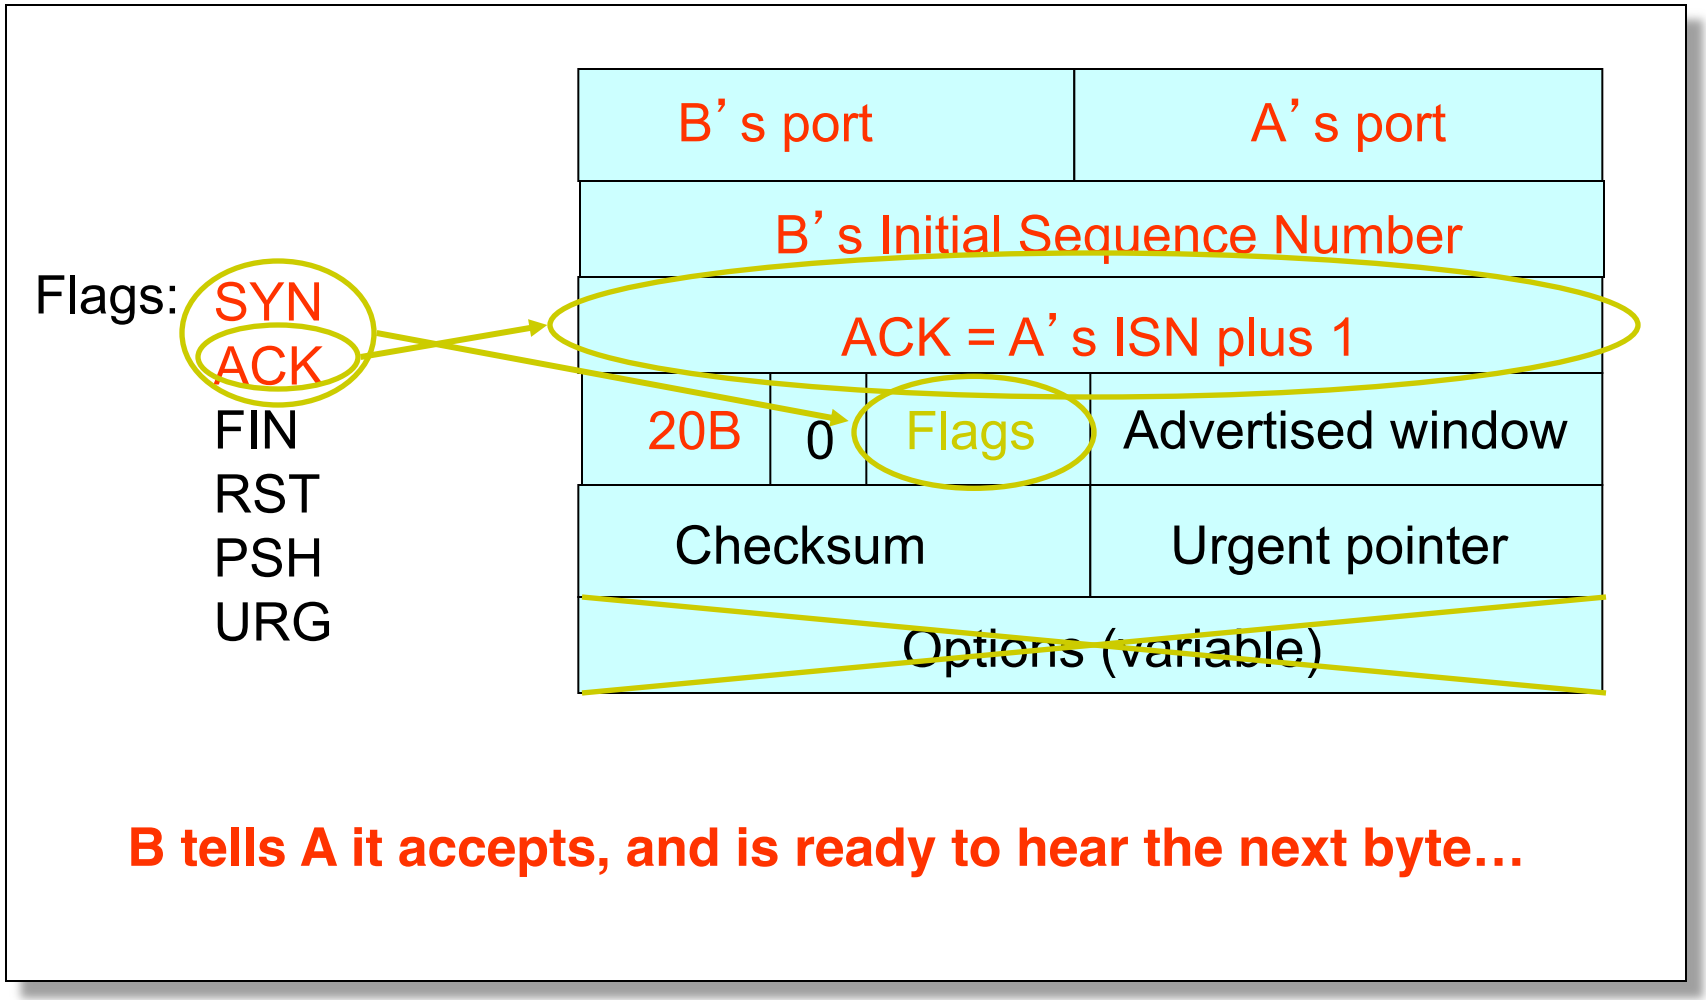
Options (variable)
Data

# Step 1: A's Initial SYN Packet



**A tells B it wants to open a connection…**

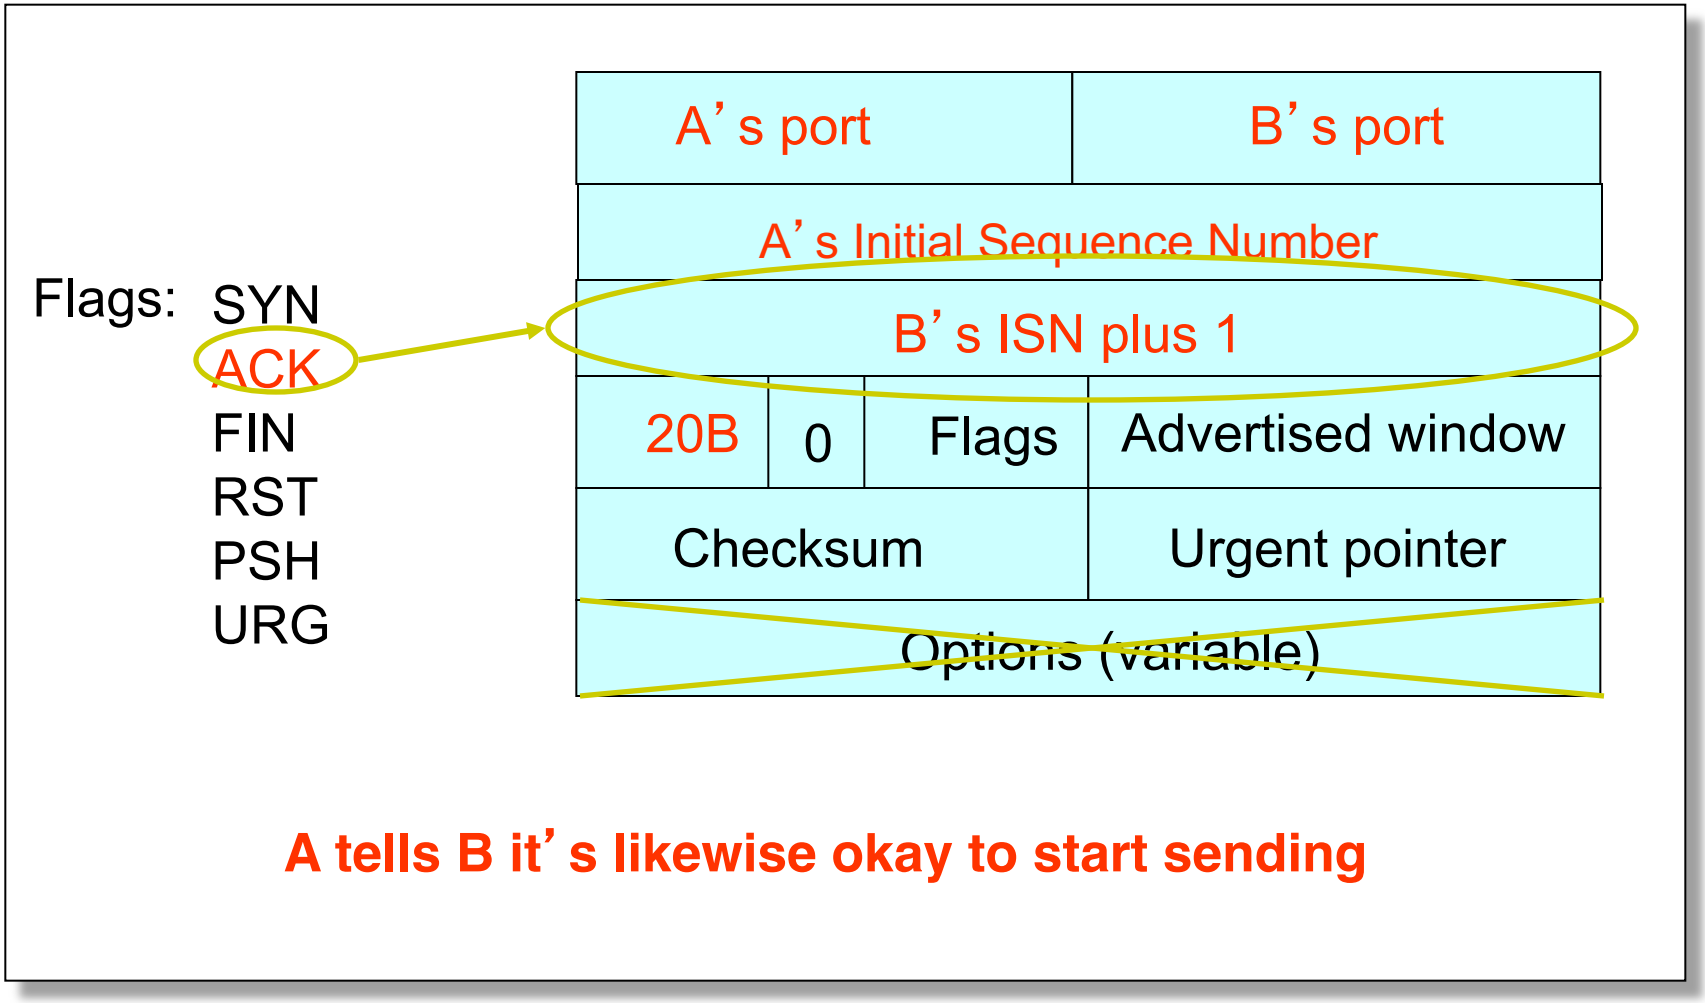
# Step 2: B's SYN-ACK Packet



**B tells A it accepts, and is ready to hear the next byte…**

**… upon receiving this packet, A can start sending data**

# Step 3: A's ACK of the SYN-ACK

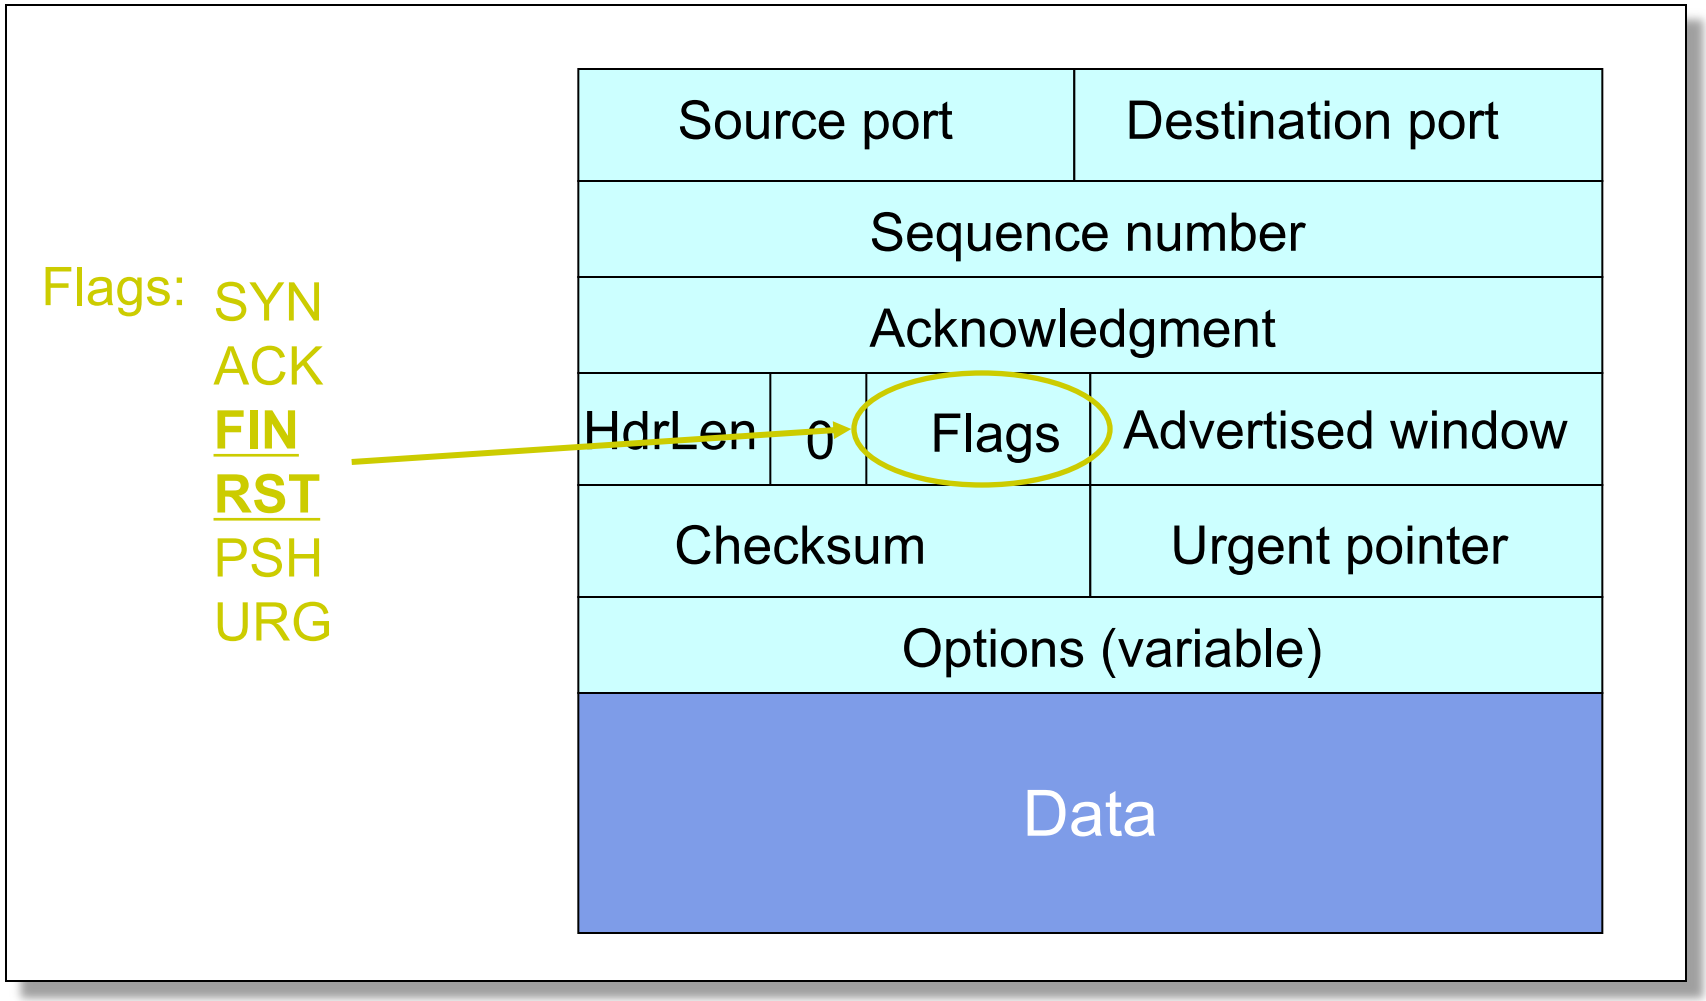


**A tells B it's likewise okay to start sending**

**… upon receiving this packet, B can start sending data**

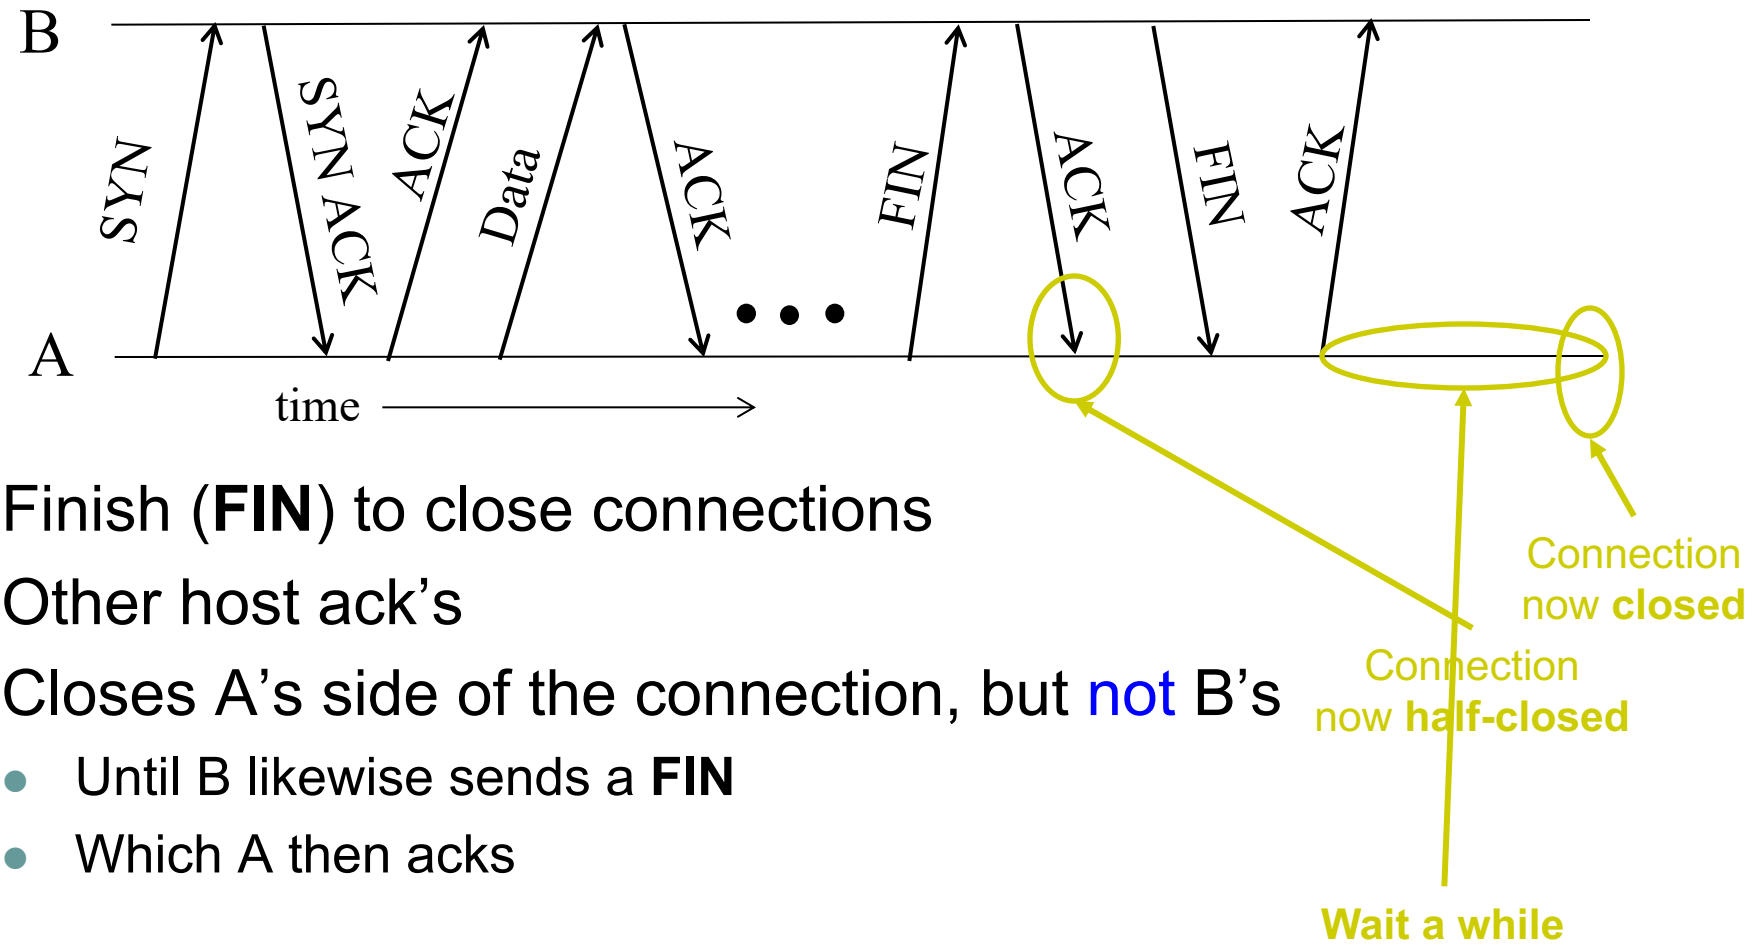
# Tearing Down the Connection

# TCP Header



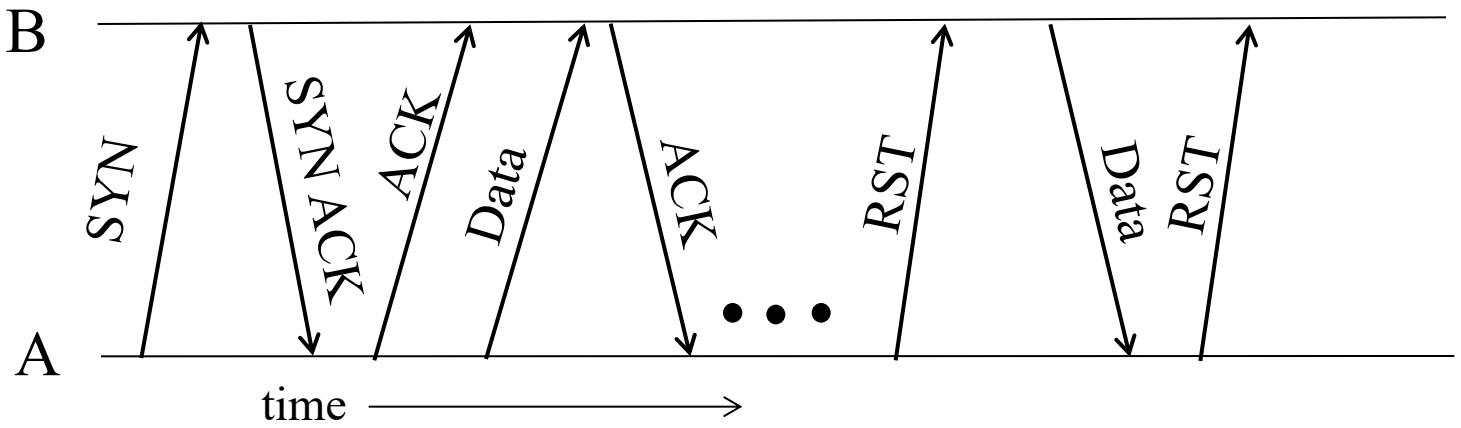
See /usr/include/netinet/tcp.h on Unix Systems

# Normal Termination, One Side At A Time



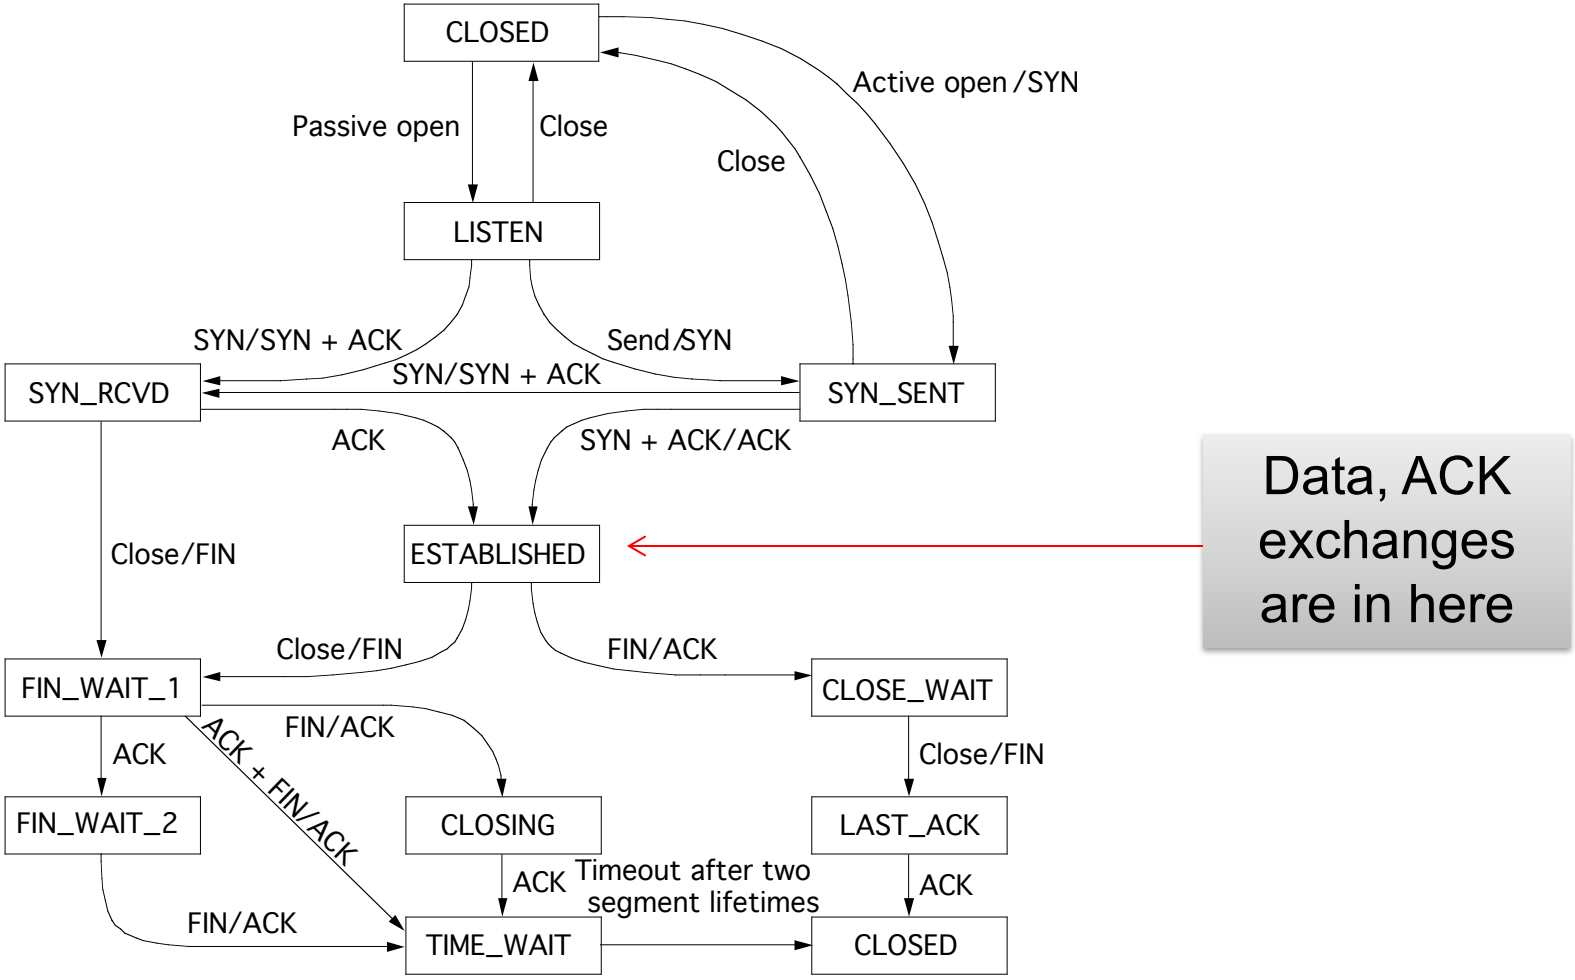
- Finish (**FIN**) to close connections
- Other host ack's
- Closes A's side of the connection, but not B's
  - Until B likewise sends a **FIN**
  - Which A then acks

# Abrupt Termination



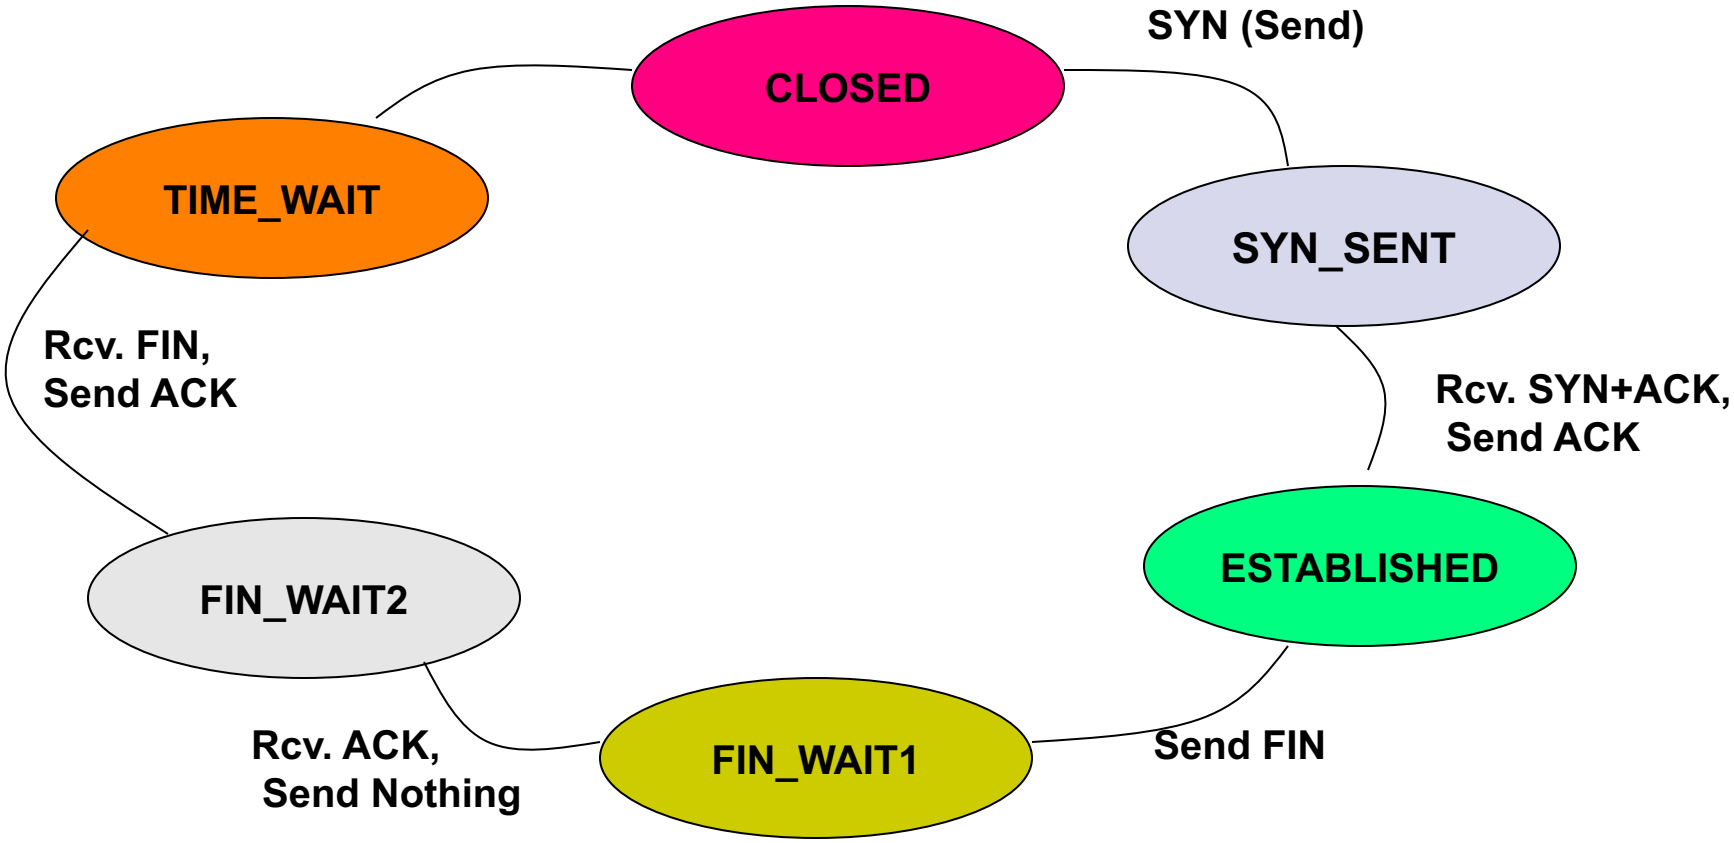
- A sends a RESET (**RST**) to B
  - E.g., because A restarted
- That's it
  - B does not ack the **RST**
  - Thus, **RST** is not delivered reliably
  - And: any data in flight is lost
  - If B sends anything more, will elicit another **RST**

# TCP State Transitions



Data, ACK exchanges are in here

# An Simpler View of the Client Side



# In Summary

- **TCP**
  - An elegant (though not perfect) piece of engineering that has stood the test of time
    - Thought experiment: will TCP continue to be a good solution?
  - Plenty of evolution in individual pieces
    - **Congestion control**
    - Better acknowledgements, ISN selection, timer estimation, *etc.*
  - But core architectural decisions/abstractions remain
    - Bytestreams, connection oriented, windows etc.

- Next time: start on congestion control!

# Any Questions?
